

# INTRODUCTION TO OBJECT-ORIENTED PROGRAMMING

## WEEK 10

# Inheritance with Java

## Part 1

**Nurnasran Puteh**

*The Eminent Management University*

# INTRODUCTION TO OBJECT-ORIENTED PROGRAMMING

## Outline

- Types of inheritance
- Defining child class in Java

## Learning Objectives

- To differentiate between single and multiple inheritance
- To define a child class in Java using `extends` keyword

# There are two types of Inheritances

## Single inheritance

a child class can be derived from a **single/one** parent class only

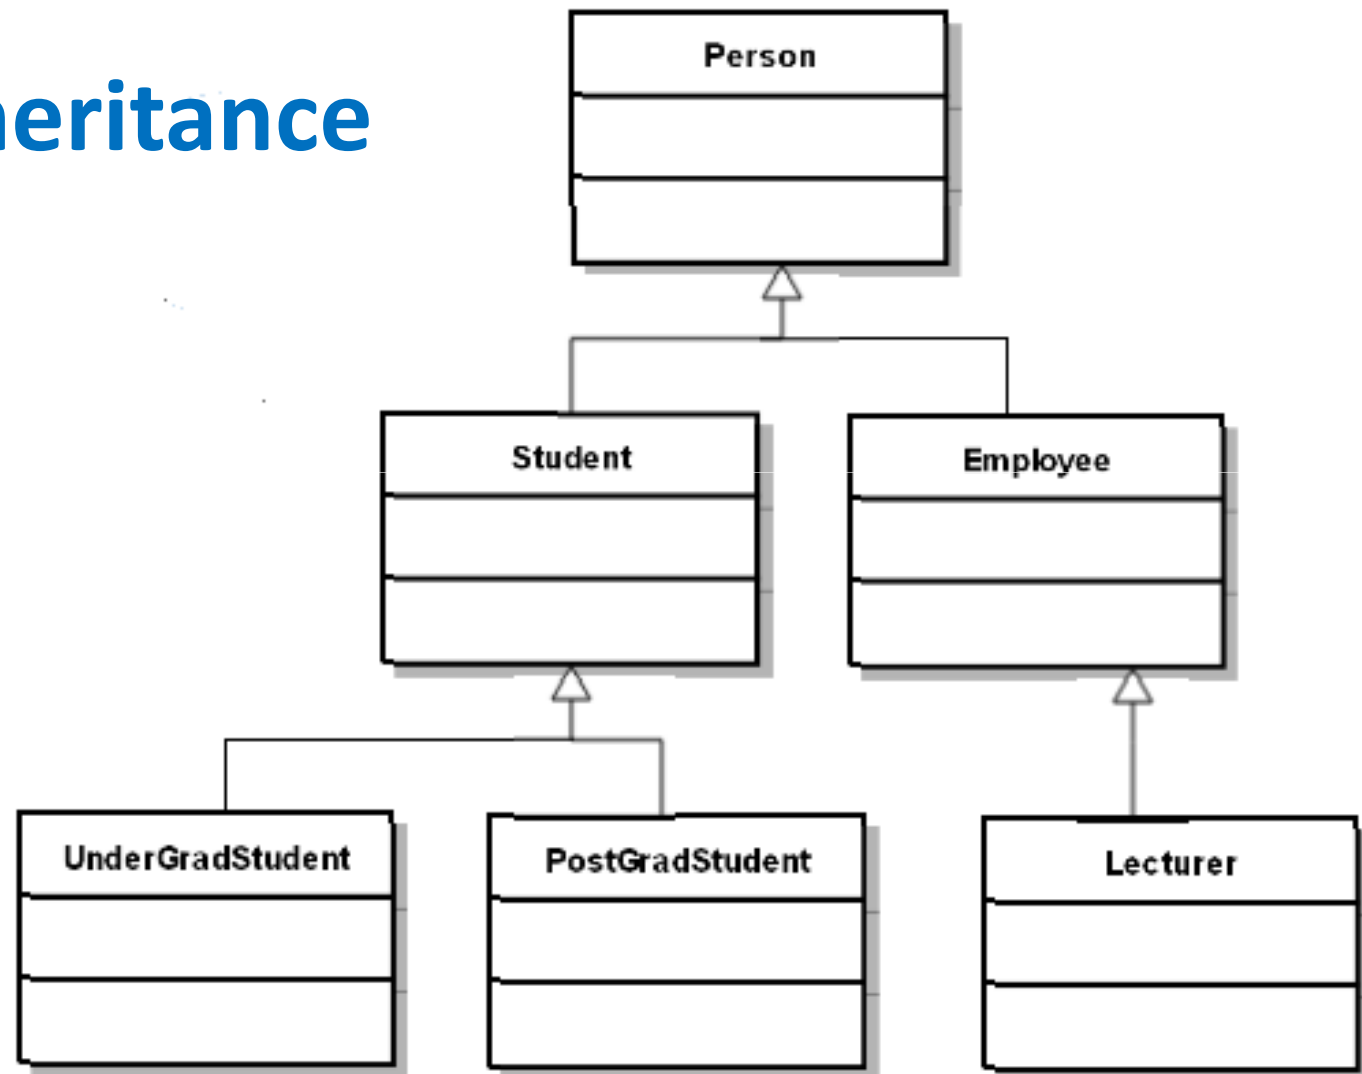

## Multiple inheritance

a child class can be derived from **more than one** parent class

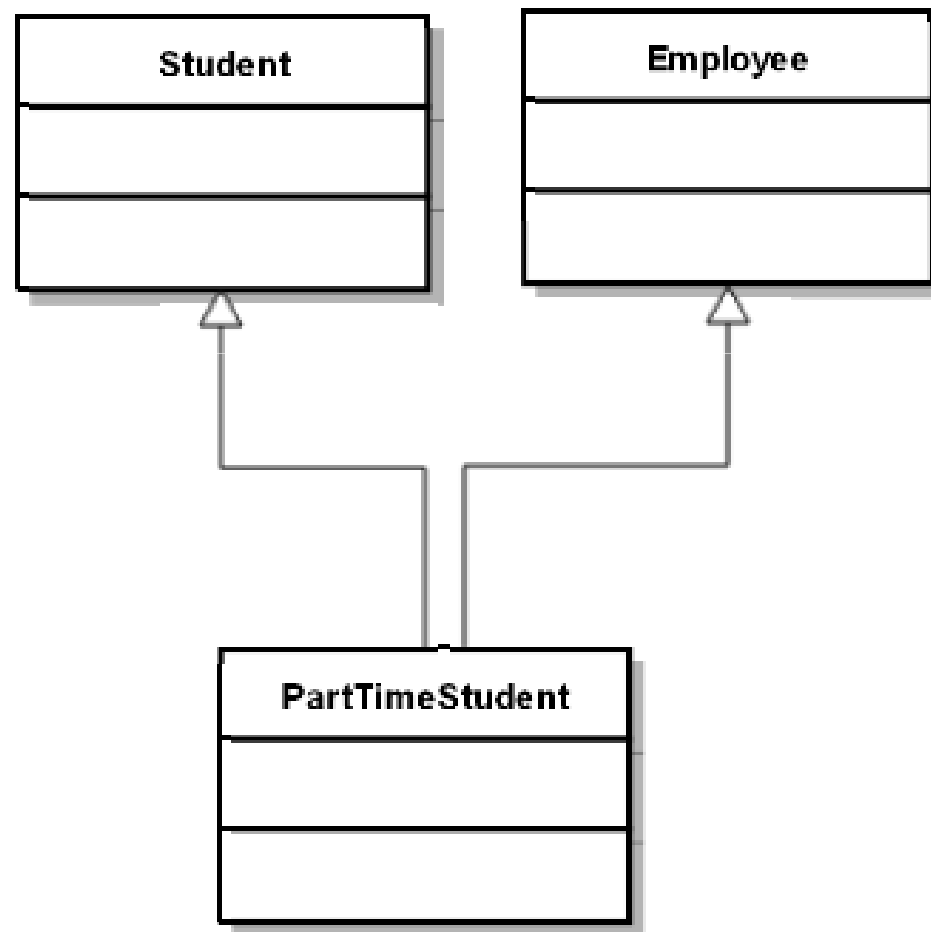

## Single Inheritance

# Multiple Inheritance

## INTRODUCTION TO OBJECT-ORIENTED PROGRAMMING

# Type of inheritance in

Java only supports single  
inheritance!

# Inheritance with Java

## How to define a class is a child of a parent class?

- Use the Java **extends** keyword .
- A child class is said to extend the parent class because it inherits properties from the parent and can add more new properties of its own

# The **extends** keyword

Syntax:

```
class <ChildClassName> extends <ParentClassName>
{
    // data & methods specific to child
}
```

Example:

```
public class Student extends Person {
    //data & method definitions
}
```

## First, define the parent class Person

Person
-name : String -age : int
+setName (String) : void +setAge(int) : void +getName() : String +getAge() : int

## Parent class: Person

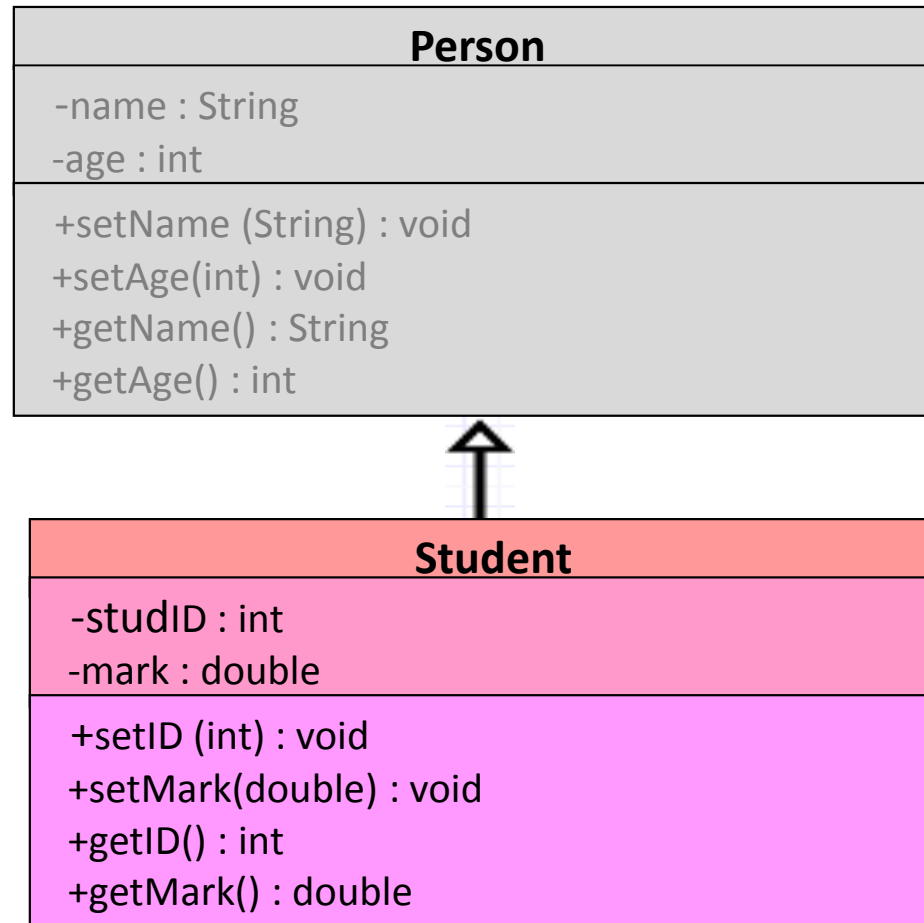

```
public class Person {  
  
    private String name;  
    private int age;  
  
    public void setName(String name) {  
        this.name = name;  
    }  
  
    public void setAge(int age) {  
        this.age = age;  
    }  
  
    public String getName() {  
        return name;  
    }  
  
    public int getAge() {  
        return age;  
    }  
}
```

# INTRODUCTION TO OBJECT-ORIENTED PROGRAMMING

Next,  
define  
the child  
class  
Student

## Child class: Student

```
public class Student extends Person {  
    private int studID;  
    private double mark;  
  
    public void setID(int matric) {  
        this.studID = matric;  
    }  
  
    public void setMark(double mark) {  
        this.mark = mark;  
    }  
  
    public int getID() {  
        return studID;  
    }  
  
    public double getMark() {  
        return mark;  
    }  
}
```

# INTRODUCTION TO OBJECT-ORIENTED PROGRAMMING

Next, we  
write a  
test  
program

```
public class TestProgram {  
  
    public static void main(String[] args) {  
        Person p1 = new Person();  
        Student s1 = new Student();  
  
        p1.setName("Ali");  
        p1.setAge(30);  
  
        s1.setName("Siti");  
        s1.setAge(19);  
        s1.setID(11111);  
        s1.setMark(95);  
  
        System.out.println("Person name is "+p1.getName());  
        System.out.println("Person age is "+p1.getAge());  
        System.out.println("Student name is "+s1.getName());  
        System.out.println("Student age is "+s1.getAge());  
        System.out.println("Student ID is "+s1.getID());  
        System.out.println("Student mark is "+s1.getMark());  
    }  
}
```

## INTRODUCTION TO OBJECT-ORIENTED PROGRAMMING

### Output:

```
run:
```

```
Person name is Ali
```

```
Person age is 30
```

```
Student name is Siti
```

```
Student age is 19
```

```
Student ID is 11111
```

```
Student mark is 95.0
```

```
BUILD SUCCESSFUL (total time: 1 second)
```

## Summary

- There are two types of inheritance: single and multiple inheritance
- Java only supports single inheritance
- Use the Java 'extends' keyword in the header of the class definition to define a child class
